## UTILITY PATENT APPLICATION TRANSMITTAL

(Only for new nonprovisional applications under 37 CFR 1.53(b))

### APPLICATION ELEMENTS

See MPEP chapter 600 concerning utility patent application contents.

1.  Fee Transmittal Form (e.g., PTO/SB/17)  
(Submit an original and a duplicate for fee processing)
2.  Applicant claims small entity status.  
See 37 CFR 1.27.
3.  Specification [Total Pages 31] (preferred arrangement set forth below)
  - Descriptive title of the invention
  - Cross Reference to Related Applications
  - Statement Regarding Fed sponsored R & D
  - Reference to sequence listing, a table, or a computer program listing appendix
  - Background of the Invention
  - Brief Summary of the Invention
  - Brief Description of the Drawings (if filed)
  - Detailed Description
  - Claim(s)
  - Abstract of the Disclosure
4.  Drawing(s) (35 U.S.C. 113) [Total Sheets 2]
5. Oath or Declaration [Total Pages       ]
  - a.  Newly executed (original or copy)
  - b.  Copy from a prior application (37 CFR 1.63 (d)) (for continuation/divisional with Box 17 completed)
    - i.  **DELETION OF INVENTOR(S)**  
Signed statement attached deleting inventor(s) named in the prior application, see 37 CFR 1.63(d)(2) and 1.33(b)
6.  Application Data Sheet. See 37 CFR 1.76

17. If a CONTINUING APPLICATION, check appropriate box, and supply the requisite information below and in a preliminary amendment, or in an Application Data Sheet under 37 CFR 1.76:

Continuation     Divisional     Continuation-in-part (CIP)

of prior application No. \_\_\_\_\_ / \_\_\_\_\_

Prior application information: Examiner \_\_\_\_\_

Group / Art Unit. \_\_\_\_\_

For CONTINUATION OR DIVISIONAL APPS only: The entire disclosure of the prior application, from which an oath or declaration is supplied under Box 5b, is considered a part of the disclosure of the accompanying continuation or divisional application and is hereby incorporated by reference. The incorporation can only be relied upon when a portion has been inadvertently omitted from the submitted application parts.

PATENT TRADEMARK OFFICE

164.1012.01

1        This application is submitted in the name of the following inventors:

2

3 <u>Inventor</u>	4 <u>Citizenship</u>	5 <u>Residence City and State</u>
6        Subir VARMA	7        United States	8        San Jose, CA

9

10        The assignee is *Aperto Networks, Inc.*, a corporation having an office at 1637  
11        South Main Street, Milpitas CA 95035.

12        Title of the Invention

13        Contention Control with State Machine

14        Background of the Invention

15        A portion of the disclosure of this patent document contains material which is  
16        subject to copyright protection. The copyright owner has no objection to the facsimile  
17        reproduction by anyone of the patent document or the patent disclosure, as it appears in the  
18        Patent and Trademark Office patent file or records, but otherwise reserves all copyright rights  
19        whatsoever.

20

21        *1. Field of the Invention*

22

23        This invention relates to point-to-multipoint communication. In particular, the  
24        invention relates to control of contention for data slots by customer premises equipment in a  
25        wireless point-to-multipoint communication system.

1

2 *2. Description of the Related Art*

3

4       In a point-to-multipoint network, plural customer provided equipment (CPEs)  
5 communicate bidirectionally with a base station controller (BSC) in a cell. Several CPEs can  
6 share a single channel for communicating with the BSC. The CPEs and the BSC use time  
7 division duplexing (TDD) to facilitate the bidirectional aspect of the communication. The CPEs  
8 and the BSC use time division multiple access (TDMA) to facilitate sharing of a channel among  
9 plural CPEs.

10

11

12

13

14       In TDMA, the BSC grants data slots to the CPEs. Because multiple CPEs share a  
15 limited number of data slots, the CPEs and the BSC must negotiate data slot assignments through  
16 a process called contention.

17

18

19

20       In contention, CPEs that have upstream data to send to the BSC first send a short  
21 request (REQ) message to the BSC. The BSC responds with a grant of a data slot for use by the  
22 CPE.

1           One technique used in the prior art to reduce contention traffic is called  
2           piggybacking. In piggybacking, a CPE first requests a data slot. When the data slot is granted by  
3           the BSC, the CPE sends data packets upstream. The CPE attaches a size of its current data  
4           backlog to a header for one of the data packets. As a result, whenever the backlog is non-zero,  
5           the BSC knows to grant a data slot to the CPE without the CPE having to send a REQ message.  
6           Thus, contention traffic is reduced.

7  
8           Unfortunately, piggybacking is only effective if upstream traffic from the CPE is  
9           of the bursty type, so that the CPE needs to make only one contention request per burst.  
10           However, some important traffic sources are non-bursty. Examples of non-bursty traffic include  
11           traffic generated by online games and voice sources. Even ordinary Internet traffic running over  
12           TCP becomes non-bursty when a communication link is in heavy traffic. In the presence of  
13           non-bursty traffic, the piggyback scheme breaks down, and an excessive number of contention  
14           requests are sent upstream.

15  
16           Summary of the Invention  
17  
18

19           In view of the foregoing, further reducing contention traffic is desirable, especially  
20           for non-bursty traffic. The invention addresses this need by using a new state machine to control  
21           a contention state for a communication link between a base station controller and customer  
22           premises equipment in point-to-multipoint communication. According to the invention, the state  
23           machine includes a grant pending absent state in which the customer premises equipment is  
24           polled with a unicast request slot. During the grant pending absent state, the customer premises  
25           equipment sends no upstream data to the base station controller but can use the unicast request  
          slot to request a data slot for sending upstream data to the base station controller.

1

2                   By virtue of the grant pending absent state, the customer premises equipment can  
3                   request a data slot without entering into contention and generating excess contention traffic.  
4                   After a suitable delay without more data being received to send upstream, the state machine can  
5                   exit the grant pending absent state. This delay preferably is long enough for receipt of new non-  
6                   bursty data for a communication, for example 50 ms.

7

8                   The state machine preferably also includes an idle state in which the customer  
9                   premises equipment awaits arrival of data packets to send as upstream data to the base station  
10                  controller, a deferring state in which the customer premises equipment requests grant of a data  
11                  slot for sending upstream traffic to the base station controller and if necessary defers contending  
12                  for the data slot so as to avoid collisions with other customer premises equipment, and a grant  
13                  pending state in which the customer premises equipment awaits and receives grant of the data  
14                  slot for sending upstream data to the base station controller and sends upstream data to the base  
15                  station controller after grant of the data slot.

16

17

18                  In a preferred embodiment of the invention, the customer premises equipment  
19                  uses piggybacking to request grant of a next data slot while sending upstream data to the base  
20                  station controller. Use of piggybacking along with the grant pending absent state has been found  
21                  to decrease drastically contention traffic.

22

23

24

25

26

27

28

29                  Preferably, the state machine enters the deferring state upon arrival of data packets  
30                  to send as upstream data to the base station controller. In the preferred embodiment, the state  
31                  machine enters the grant pending state after the deferring state, returns to the deferring state if a  
32                  collision occurs, and remains in the grant pending state when sending upstream data to the base

1 station controller with piggybacking. The state machine preferably enters the grant pending  
2 absent state after the customer premises equipment has sent upstream data to the base station  
3 controller in the grant pending state.

4

5 The state machine according to the invention preferably also includes an  
6 unsolicited grant pending state in which the customer premises equipment receives grant of the  
7 data slot for sending upstream data to the base station controller and sends upstream data to the  
8 base station controller after grant of the data slot, without having requested the data slot. The  
9 state machine preferably further includes an unsolicited grant pending absent state in which the  
10 customer premises equipment is polled with the unicast request slot. During the unsolicited grant  
11 pending absent state, the customer premises equipment sends no upstream data to the base station  
12 controller but can use the unicast request slot to request the data slot for sending upstream data to  
13 the base station controller. Preferably, the state machine enters the unsolicited grant pending  
14 absent state after the customer premises equipment has sent upstream data to the base station  
15 controller in the unsolicited grant pending state.

16  
17  
18  
19  
20  
21  
22  
23  
24  
25

26 The invention can be embodied in a method for controlling communication using  
27 the state machine described above, as well as in software and/or hardware such as a base station  
28 controller and/or customer premises equipment that implements the method, and in various other  
29 embodiments.

30

31 This brief summary has been provided so that the nature of the invention may be  
32 understood quickly. A more complete understanding of the invention may be obtained by  
33 reference to the following description of the preferred embodiments thereof in connection with  
34 the attached drawings.

herein. This application claims priority of each of these documents. These documents are  
collectively referred to as the “Incorporated Disclosures.”

*Lexicography*

The following terms refer or relate to aspects of the invention as described below.  
The descriptions of general meanings of these terms are intended to be illustrative, not limiting.

1       **base station controller (BSC)** — in general, a device for performing coordination and  
2       control for a wireless communication cell. There is no particular requirement that the base  
3       station controller must be a single device; in alternative embodiments, the base station  
4       controller can include a portion of a single device, a combination of multiple devices, or  
5       some hybrid thereof.

6

7       **communication link** — in general, an element for sending information from a sender to a  
8       recipient. Although in a preferred embodiment the communication links referred to are  
9       generally wireless line of sight point to point communication links, there is no particular  
10      requirement that they are so restricted.

11

12

13

14

15

16

17

18

19       **customer premises equipment (CPE)** — in general, a device for performing  
20       communication processes and tasks at a customer location, and operating in conjunction  
21       with the base station controller within a wireless communication cell. There is no  
22       particular requirement that the customer premises equipment must be a single device; in  
23       alternative embodiments, the customer premises equipment can include a portion of a  
24       single device, a combination of multiple devices, or some hybrid thereof.

1

2 The context of the invention is similar to that of the Incorporated Disclosures.

3

4 A system using point-to-multipoint communication in a wireless communication  
5 system operates as part of a system in which devices coupled to a network (such as a computer  
6 network) send messages, route and switch messages, and receive messages. In a preferred  
7 embodiment, devices coupled to (and integrated with) the network send, route, and receive these  
8 messages as sequences of packets, each of which has a header including delivery information and  
9 a payload including data. In a preferred embodiment, packet format conforms to the OSI model,  
10 in which an application protocol (layer 5, such as FTP) uses a transport protocol (layer 4, such as  
11 TCP), which uses a network protocol (layer 3, such as IP), which uses a media access control  
12 (MAC) protocol (layer 2), which uses a physical transport technique (layer 1).

13

14 *System Elements*

15

16 Fig. 1 is a block diagram of a wireless communication system according to the  
17 invention in which a base station controller communicates with one or more customer premises  
18 equipment according to the invention.

19

20 System 10 includes wireless communication cell 11 (or a portion thereof), base  
21 station controller (BSC) 12, and one or more customer premises equipment (CPE) 13.

22

23 Wireless communication cell 11 preferably includes a generally hexagon-shaped  
24 region of local surface area, such as might be found in a metropolitan region. Use of generally  
25 hexagon-shaped regions is known in the art of wireless communication because hexagonal  
26 regions are able to tile a local region with substantially no gaps. Although in a preferred  
embodiment wireless communication cell 11 includes a generally hexagon-shaped region, no

1 particular requirement exists for using that particular shape; in alternative embodiments, another  
2 shape or tiling of the local surface area may be useful.

3

4 In Fig. 1, a portion of cell 11 includes a generally triangular-shaped region of local  
5 surface area, herein called a “sector.” Sectors 14 preferably are disposed so that a set of six  
6 sectors 14 combine to form single cell 11. Thus, BSC 12 preferably is disposed at or near one  
7 corner of one of sectors 14, while CPEs 13 are disposed within the sectors.

8

9 Although the invention is primarily described with regard to interactions that  
10 occur between BSC 12 and a single CPE 13 in a single sector 14, substantial applications of the  
11 invention exist for interactions across multiple sectors within a cell, and to interaction across  
12 sectors in multiple cells. Substantial applications of the invention with regard to multiple  
13 sectors, both within single cell and among multiple cells, would be clear to those skilled in the art  
14 of wireless communication after perusal of this application, and would not require undue  
15 experimentation or further invention.

16

17 BSC 12 preferably includes a processor, program and data memory, mass storage,  
18 and one or more antennas for sending or receiving information using wireless communication  
19 techniques.

20

21 Similar to BSC 12, each CPE 13 preferably includes a processor, program and  
22 data memory, mass storage, and one or more antennas for sending or receiving information using  
23 wireless communication techniques.

24

25 In system 10, plural CPEs 13 communicate bidirectionally with BSC 12. Several  
26 CPEs 13 can share a single channel for communicating with BSC 12. BSC 12 and CPEs 13

1 preferably use time division duplexing (TDD) to facilitate the bidirectional aspect of the  
2 communication. BSC 12 and CPEs 13 preferably use time division multiple access (TDMA) to  
3 facilitate sharing of a channel among plural CPEs 13.

4

5 In TDMA, BSC 12 grants data slots to CPEs 13. Because multiple CPEs 13 share  
6 a limited number of data slots, CPEs 13 and BSC 12 must negotiate data slot assignments through  
7 a process called contention.

8

9 In contention, CPEs 13 that have upstream data to send to BSC 12 first send a  
10 short request (REQ) message to BSC 12. The BSC responds with a grant of a data slot for use by  
11 the CPE.

12

13 Problems can arise in contention. Plural CPEs 13 might simultaneously try to use  
14 a single request slot to request data slots. This situation is called collision. When collisions  
15 occur, none of the CPE's request messages successfully reach BSC 12. Those CPEs 13 have to  
16 re-send their REQ messages. In order to try to allow REQ traffic to clear, CPEs 13 according to  
17 the invention can defer re-sending REQ messages for some period of time when collisions occur.

18

19 If many request slots are defined so as to reduce a number of collisions and so as  
20 to facilitate requests by a large number of CPEs 13, or if too many REQ messages have to be re-  
21 sent, too much of available bandwidth can be used up by contention traffic. As a result, data  
22 throughput can be unacceptably decreased.

23

24 One technique used in the prior art to reduce contention traffic is called  
25 piggybacking. In piggybacking, CPE 13 first requests a data slot. When the data slot is granted  
26 by BSC 12, CPE 13 sends data packets upstream. CPE 13 attaches a size of its current data

1 backlog to a header for one of the data packets. As a result, whenever the backlog is non-zero,  
2 BSC 12 knows to grant a data slot to CPE 13 without CPE 13 having to send a REQ message.  
3 Thus, contention traffic is reduced.

4

5         Unfortunately, piggybacking is only effective if upstream traffic from CPE 13 is  
6 of the bursty type, so that CPE 13 needs to make only one contention request per burst.  
7 However, some important traffic sources are non-bursty. Examples of non-bursty traffic include  
8 traffic generated by online games and voice sources. Even ordinary Internet traffic running over  
9 TCP becomes non-bursty when a communication link is in heavy traffic. In the presence of  
10 non-bursty traffic, the piggyback scheme breaks down, and an excessive number of contention  
11 requests are sent upstream.

12

13         The invention attempts to reduce contention traffic by using a new state machine  
14 to control a contention state for a communication link between a base station controller and  
15 customer premises equipment in point-to-multipoint communication. The state can be controlled  
16 by the CPE, the BSC, or both.

17

18         Fig. 2 is a flow chart of a state machine according to the invention.

19

20         Briefly, according to the invention, the state machine includes a grant pending  
21 absent state in which the customer premises equipment is polled with a unicast request slot.  
22 During the grant pending absent state, the customer premises equipment sends no upstream data  
23 to the base station controller but can use the unicast request slot to request a data slot for sending  
24 upstream data to the base station controller.

1 By virtue of the grant pending absent state, the customer premises equipment can  
2 request a data slot without entering into contention and generating excess contention traffic.  
3 After a suitable delay without more data being received to send upstream, the state machine can  
4 exit the grant pending absent state. This delay preferably is long enough for receipt of new non-  
5 bursty data for a communication, for example 50 ms.

6

7 In more detail, Fig. 2 shows a state machine that includes idle state 20, deferring  
8 state 21, grant pending state 22, grant pending absent state 23, unsolicited grant pending state 24,  
9 and unsolicited grant pending absent state 25. While the particular states shown in Fig. 2 are  
10 representative of a preferred embodiment of the invention, the invention also can utilize state  
11 machines that do not include all of these states and/or that include additional states.

12

13 Idle state 20 is a waiting state in which the customer premises equipment awaits  
14 arrival of data packets to send as upstream data to the base station controller.

15

16 Upon arrival of data to be sent as upstream data, the state machine transitions to  
17 deferring state 21. The state machine also can transition to unsolicited grant pending state 24  
18 upon receipt of an unsolicited grant of a data slot from BSC 24, as discussed below.

19

20 In deferring state 21, CPE 13 sends a REQ message to BSC 12. The state  
21 machine then transitions to grant pending state 22. However, if no grant is received from BSC  
22 12 in grant pending state 22 before a timeout, the state machine returns to deferring state 21, as  
23 discussed below.

24

25 One possible reason for non-receipt of a grant is a collision with another CPE 13.  
26 Thus, deferral is needed, and CPE 13 defers sending a new REQ message for a period of time.

1 The CPE then sends the new REQ message. In a preferred embodiment, if another collision  
2 occurs, CPE 13 again defers sending another REQ message. This process preferably continues  
3 until the REQ messages gets through to BSC 12 (as evidenced by receipt of a grant) or until an  
4 error is generated (not shown).

5

6 Preferably, each time CPE 13 defers sending a REQ message, the period of  
7 deferral roughly doubles, with a random factor included to try to avoid deferring in synch with  
8 another CPE. Thus, in deferring state 21, CPE 13 defers contending for a data slot so as to avoid  
9 collisions with other customer premises equipment.

10

11 In grant pending state 22, CPE 13 awaits and receives grant of the data slot for  
12 sending upstream data to the base station controller and sends upstream data to the base station  
13 controller after grant of the data slot. However, if a grant is not received before a timeout, the  
14 CPE concludes that a collision or some other error has occurred, and the state machine returns to  
15 deferring state 21.

16

17

18 Preferably, in grant pending state 22, CPE 13 uses piggybacking to request grant  
19 of a next data slot while sending upstream data to BSC 12. When CPE 13 sends the last data in  
20 its backlog, that data preferably is sent without piggybacking. The state machine then transitions  
21 to grant pending absent state 23 according to the invention.

22

23

24

25

26

27 During grant pending absent state 23, CPE 13 sends no upstream data to BSC 12.  
28 No grant is pending because piggybacking was not used in the previous transmission of data to  
29 BSC 12 (hence the name of the state). Rather, CPE 13 is periodically (e.g., every 10 ms) polled  
30 by BSC 12 with a unicast request slot. CPE 13 can use this unicast request slot to request a data  
31 slot for sending upstream data to the base station controller. Thus, if more data is received by

1 CPE 13 to send upstream to BSC 12, CPE 13 can request a data slot without going through  
2 contention, thereby reducing contention traffic.

3

4 In some circumstances, the reduction in contention traffic can be drastic, for  
5 example by an order of magnitude. Of course, the invention is not limited to such circumstances  
6 and is not limited to such drastic reductions in contention traffic.

7

8 Upon grant of a data slot for sending new data to BSC 12, CPE 13 returns to grant  
9 pending state 22.

10

11

12 If no new data is received by CPE 13 before a timeout in grant pending absent  
13 state 23, the state machine returns to idle state 20. A timeout of 50 ms has been found to work  
14 well.

15

16

17 In some circumstances, BSC 12 can grant a data slot to CPE 13 without the CPE  
18 having requested the data slot. For example, if the communication between BSC 12 and CPE 13  
19 is a voice communication, BSC 12 can predict that CPE 13 will need data slots. BSC 12 can  
20 grant those data slots to CPE 13 without CPE 13 having to request them. Such a grant is an  
21 unsolicited grant.

22

23

24 Accordingly, the preferred embodiment of the state machine according to the  
25 invention also includes unsolicited grant pending state 24 and unsolicited grant pending absent  
state 25. These states correspond to grant pending state 22 and grant pending absent state 23,  
respectively, with the exception that they are entered when an unsolicited grant occurs.

1           Thus, in unsolicited grant pending state 24, CPE 13 receives grant of the data slot  
2        for sending upstream data to the base station controller and sends upstream data to the base  
3        station controller after grant of the data slot, without having requested the data slot.

4

5           In unsolicited grant pending absent state 25, CPE 13 is polled with the unicast  
6        request slot. During unsolicited grant pending absent state 25, CPE 13 sends no upstream data to  
7        BSC 12 but can use the unicast request slot to request the data slot for sending upstream data to  
8        BSC 12. The state machine enters unsolicited grant pending absent state 25 after CPE 12 has  
9        sent upstream data to BSC 12 in unsolicited grant pending state 24.

Pseudo-code for implementing the preferred embodiment of the invention  
substantially as discussed above is included in a technical appendix to this application.

#### *Alternative Embodiments*

The invention can be embodied in a method for controlling communication using  
the state machine described above, as well as in software and/or hardware such as a BSC and/or a  
CPE that implements the method, and in various other embodiments.

In the preceding description, a preferred embodiment of the invention is described  
with regard to preferred process steps and data structures. However, those skilled in the art  
would recognize, after perusal of this application, that embodiments of the invention may be  
implemented using one or more general purpose processors or special purpose processors  
adapted to particular process steps and data structures operating under program control, that such  
process steps and data structures can be embodied as information stored in or transmitted to and  
from memories (e.g., fixed memories such as DRAMs, SRAMs, hard disks, caches, etc., and

1 removable memories such as floppy disks, CD-ROMs, data tapes, etc.) including instructions  
2 executable by such processors (e.g., object code that is directly executable, source code that is  
3 executable after compilation, code that is executable through interpretation, etc.), and that  
4 implementation of the preferred process steps and data structures described herein using such  
5 equipment would not require undue experimentation or further invention.

6

7 Furthermore, although preferred embodiments of the invention are disclosed  
8 herein, many variations are possible which remain within the content, scope and spirit of the  
9 invention, and these variations would become clear to those skilled in the art after perusal of this  
10 application.

1    Claims  
2  
33            What is claimed is:  
4  
55            1. A method of controlling a contention state for a communication link between a  
6            base station controller and customer premises equipment in point-to-multipoint communication,  
7            comprising the step of:8                    controlling the contention state using a state machine, the state machine including  
9                    a grant pending absent state in which the customer premises equipment is polled with a unicast  
10                  request slot, wherein during the grant pending absent state, the customer premises equipment  
11                  sends no upstream data to the base station controller but can use the unicast request slot to  
12                  request a data slot for sending upstream data to the base station controller.13  
14            2. A method as in claim 1, wherein the state machine further includes an idle state  
15            in which the customer premises equipment awaits arrival of data packets to send as upstream  
16            data to the base station controller.17  
18            3. A method as in claim 2, wherein the state machine further includes a deferring  
19            state in which the customer premises equipment requests grant of a data slot for sending  
20            upstream traffic to the base station controller and if necessary defers contending for the data slot  
21            so as to avoid collisions with other customer premises equipment.22  
23            4. A method as in claim 3, wherein the state machine further includes a grant  
24            pending state in which the customer premises equipment awaits and receives grant of the data  
25            slot for sending upstream data to the base station controller and sends upstream data to the base  
26            station controller after grant of the data slot.

1  
2       5. A method as in claim 4, wherein in the grant pending state, the customer  
3 premises equipment uses piggybacking to request grant of a next data slot while sending  
4 upstream data to the base station controller.

5  
6       6. A method as in claim 5, wherein the state machine enters the deferring state  
7 upon arrival of data packets to send as upstream data to the base station controller,  
8       wherein the state machine enters the grant pending state after the deferring state,  
9 returns to the deferring state if a collision occurs, and remains in the grant pending state when  
10 sending upstream data to the base station controller with piggybacking, and

11       wherein the state machine enters the grant pending absent state after the customer  
12 premises equipment has sent upstream data to the base station controller in the grant pending  
13 state.

14  
15       7. A method as in claim 6, wherein the state machine further includes an  
16 unsolicited grant pending state in which the customer premises equipment receives grant of the  
17 data slot for sending upstream data to the base station controller and sends upstream data to the  
18 base station controller after grant of the data slot, without having requested the data slot.

19       8. A method as in claim 7, wherein the state machine further includes an  
20 unsolicited grant pending absent state in which the customer premises equipment is polled with  
21 the unicast request slot,

22       wherein during the unsolicited grant pending absent state, the customer premises  
23 equipment sends no upstream data to the base station controller but can use the unicast request  
24 slot to request the data slot for sending upstream data to the base station controller, and

1           wherein the state machine enters the unsolicited grant pending absent state after  
2       the customer premises equipment has sent upstream data to the base station controller in the  
3       unsolicited grant pending state.

4

5           9. Customer premises equipment that communicates over a communication link  
6       with a base station controller in point-to-multipoint communication, comprising:

7               a transceiver, and  
8               a controller that controls a contention state for communicating over the  
9       communication link via the transceiver, the controller using a state machine for controlling the  
10      contention state, the state machine including a grant pending absent state in which the customer  
11      premises equipment is polled with a unicast request slot, wherein during the grant pending absent  
12      state, the customer premises equipment sends no upstream data to the base station controller but  
13      can use the unicast request slot to request a data slot for sending upstream data to the base station  
14      controller.

15

16           10. Customer premises equipment as in claim 9, wherein the state machine  
17      further includes an idle state in which the customer premises equipment awaits arrival of data  
18      packets to send as upstream data to the base station controller.

19

20           11. Customer premises equipment as in claim 10, wherein the state machine  
21      further includes a deferring state in which the customer premises equipment requests grant of a  
22      data slot for sending upstream traffic to the base station controller and if necessary defers  
23      contending for the data slot so as to avoid collisions with other customer premises equipment.

24

25           12. Customer premises equipment as in claim 11, wherein the state machine  
26      further includes a grant pending state in which the customer premises equipment awaits and

1 receives grant of the data slot for sending upstream data to the base station controller and sends  
2 upstream data to the base station controller after grant of the data slot.

3

4           13. Customer premises equipment as in claim 12, wherein in the grant pending  
5 state, the customer premises equipment uses piggybacking to request grant of a next data slot  
6 while sending upstream data to the base station controller.

7

8           14. Customer premises equipment as in claim 12, wherein the state machine  
9 enters the deferring state upon arrival of data packets to send as upstream data to the base station  
controller,

10           wherein the state machine enters the grant pending state after the deferring state,  
11 returns to the deferring state if a collision occurs, and remains in the grant pending state when  
12 sending upstream data to the base station controller with piggybacking, and

13           wherein the state machine enters the grant pending absent state after the customer  
14 premises equipment has sent upstream data to the base station controller in the grant pending  
15 state.

16

17           15. Customer premises equipment as in claim 14, wherein the state machine  
18 further includes an unsolicited grant pending state in which the customer premises equipment  
19 receives grant of the data slot for sending upstream data to the base station controller and sends  
20 upstream data to the base station controller after grant of the data slot, without having requested  
21 the data slot.

22

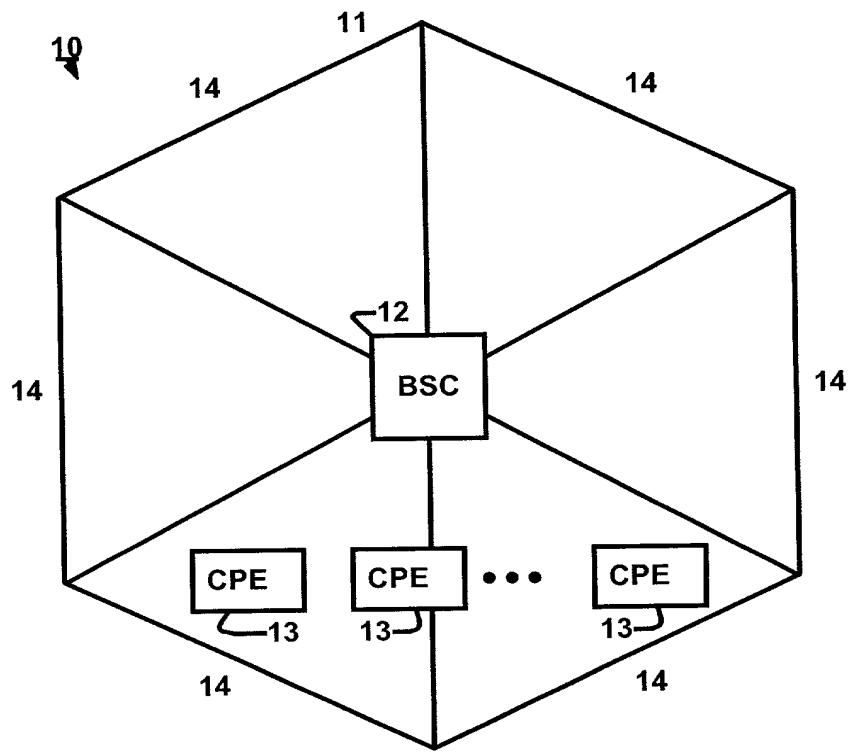

23           16. Customer premises equipment as in claim 15, wherein the state machine  
24 further includes an unsolicited grant pending absent state in which the customer premises  
25 equipment is polled with the unicast request slot,

1           wherein during the unsolicited grant pending absent state, the customer premises  
2           equipment sends no upstream data to the base station controller but can use the unicast request  
3           slot to request the data slot for sending upstream data to the base station controller, and  
4           wherein the state machine enters the unsolicited grant pending absent state after  
5           the customer premises equipment has sent upstream data to the base station controller in the  
6           unsolicited grant pending state.

1

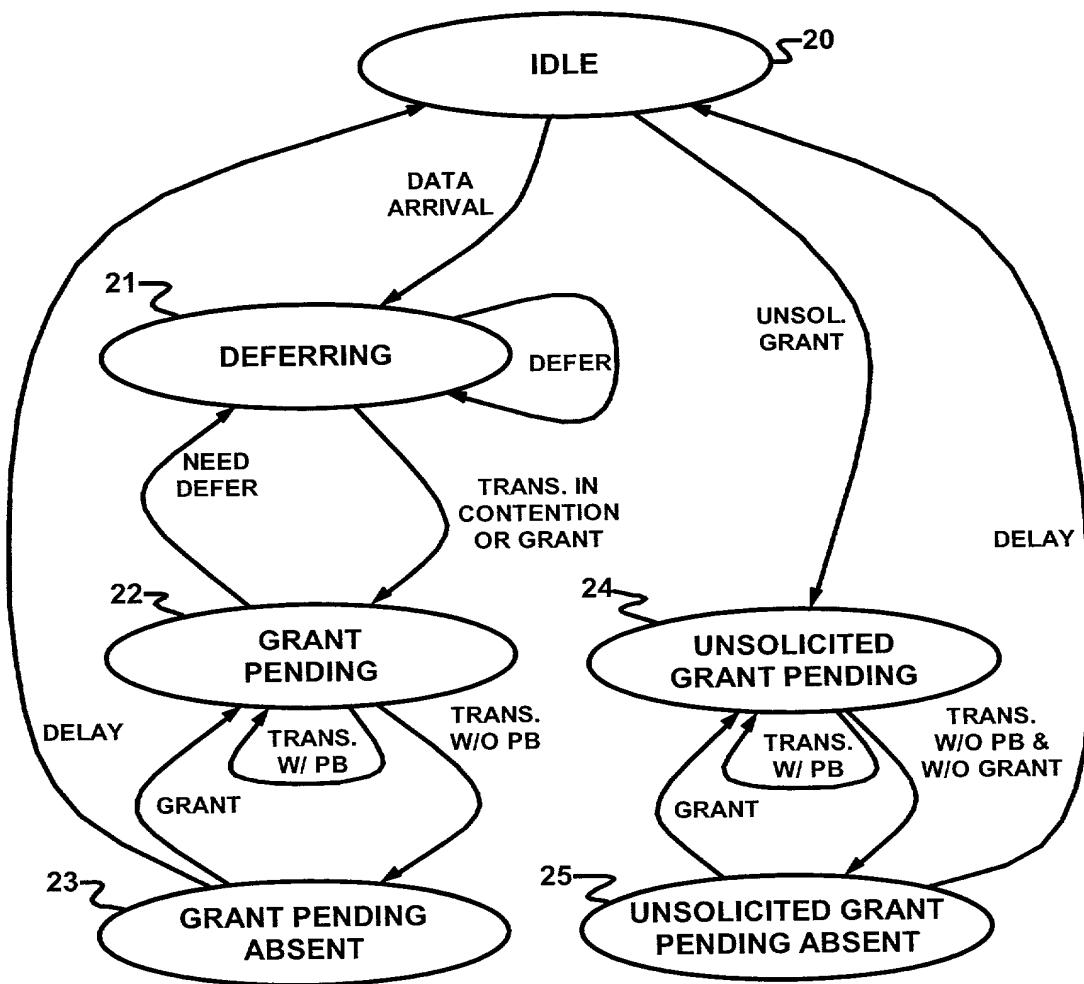

### Abstract

2           A system for controlling a contention state for a communication link between a  
3           base station controller and customer premises equipment in point-to-multipoint communication.  
4           The contention state is controlled using a state machine. The state machine includes a grant  
5           pending absent state in which a unicast request slot is maintained open for use by the customer  
6           premises equipment. During the grant pending absent state, the customer premises equipment  
7           sends no upstream data to the base station controller but can use the unicast request slot to  
8           request a data slot for sending upstream data to the base station controller. Preferably, the state  
9           machine further includes an idle state in which the customer premises equipment awaits arrival  
10           of data packets to send as upstream data to the base station controller. The state machine  
11           preferably further includes a deferring state in which the customer premises equipment defers  
12           contending for the data slot so as to avoid collisions with other customer premises equipment.  
13           The state machine also preferably includes a grant pending state in which the customer premises  
14           equipment awaits and receives grant of the data slot for sending upstream data to the base station  
15           controller and sends upstream data to the base station controller after grant of the data slot. In the  
16           grant pending state, the customer premises equipment preferably uses piggybacking to request  
17           grant of a next data slot while sending upstream data to the base station controller.
